Abstract: The penalty function method has been widely used to solve constrained optimization problems. In the method, an extended objective function, which is the sum of the objective value and the constraint violation weighted by the penalty coefficient, is optimized. However, it is difficult to control the coefficient properly because the proper control depends on each problem. Recently, the equivalent penalty coefficient (EPC) method, which is a new adaptive penalty method for population-based optimization algorithms (POAs), has been proposed. The EPC method can be applied to POAs where a new solution is compared with the old solution. The EPC value, which makes the two extended objective values of the solutions the same, is used to control the coefficient. In this study, we propose to apply the EPC method to particle swarm optimization (PSO) where a new solution is compared with the best solution found so far. In order to improve the performance of constrained optimization, a mutation operation is also proposed. The proposed method is examined using two topologies of PSO. The advantage of the proposed method is shown by solving well-known constrained optimization problems and comparing the results with those obtained by PSO with a standard constraint-handling technique.

Keywords: constrained optimization, particle swarm optimization, equivalent penalty coefficient method, population-based optimization algorithm

1. INTRODUCTION

Constrained optimization problems, especially non-linear constrained optimization problems, where objective functions are minimized under given constraints, are very important and frequently appear in the real world. There exist many studies on solving constrained optimization problems using population-based optimization algorithms (POAs) such as evolutionary algorithms (EAs)[1-3] and particle swarm optimization (PSO)[4]. POAs basically lack a mechanism to incorporate the constraints of a given problem in the fitness value of individuals. Thus, many studies have been dedicated to handle the constraints in POAs.

The penalty function method has been widely used for solving constrained optimization problems. In the method, an extended objective function is optimized where the function is defined by the sum of the objective value and the constraint violation weighted by the penalty coefficient. Feasible solutions can be found by increasing the penalty coefficient into infinity theoretically. However, it is difficult to control the coefficient properly because proper control of the coefficient varies in each problem and the search process. Recently, the equivalent penalty coefficient (EPC) method was proposed for adaptive control of the penalty coefficient in POAs [5]. An EPC value is defined in POAs where a new solution is compared with the old solution. For example, a child individual is compared with the parent individual in differential evolution (DE) and a new position after moving is compared with the personal best position found so far in PSO. The EPC value is the penalty coefficient value

that makes the two extended objective values of the old solution and the new solution the same when the objective value and the constraint violation are in a trade-off relationship. In POAs, there are plural EPCs in a population in general. Search that gives priority to the objective value and the constraint violation is realized by selecting a small EPC and a large EPC, respectively. The adaptive control of the penalty coefficient can be realized by selecting an appropriate EPC value.

In this study, we propose to apply the EPC method to PSO, whereas in [5] the EPC method was applied to DE. In order to improve the performance of constrained optimization, a mutation operation is also proposed. The proposed method is examined using two topologies of PSO such as the fully-connected topology and the ring topology. The advantage of the proposed method is shown by solving well-known constrained optimization problems and comparing the results with those obtained by PSO with a standard constraint-handling technique.

In Section 2, constrained optimization problems are defined and constrained optimization methods including the penalty function method are briefly reviewed. PSO is explained in Section 3. The proposed method is described in Section 4. In Section 5, experimental results on constrained problems are shown and the results of the proposed method are compared with those of a standard method. Finally, conclusions are described in Section 6.

2. RELATED WORKS

2.1. Constrained Optimization Problems

The general constrained optimization problem with inequality, equality, upper bound and lower bound con-

† Tetsuyuki Takahama is the presenter of this paper.

straints is defined as follows:

$$\begin{aligned} & \text{minimize} && f(\mathbf{x}), \\ & \text{subject to} && g_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, q, \\ & && h_j(\mathbf{x}) = 0, \quad j = q + 1, \dots, m, \\ & && l_i \leq x_i \leq u_i, \quad i = 1, \dots, D, \end{aligned} \quad (1)$$

where $\mathbf{x} = (x_1, x_2, \dots, x_D)$ is a D dimensional vector of decision variables, $f(\mathbf{x})$ is an objective function, $g_j(\mathbf{x}) \leq 0$ are q inequality constraints and $h_j(\mathbf{x}) = 0$ are $m - q$ equality constraints. The functions f , g_j and h_j are linear or nonlinear real-valued functions. The values u_i and l_i are the upper and lower bounds of x_i , respectively. The upper and lower bounds define the *search space* \mathcal{S} . All constraints define the *feasible region* \mathcal{F} . Feasible solutions exist in $\mathcal{F} \subseteq \mathcal{S}$.

2.2. Constrained Optimization Methods

POAs for constrained optimization can be classified into several categories according to the way the constraints are treated as follows [3]:

- (1) Constraints are only used to see whether a search point is feasible or not. Approaches in this category are usually called death penalty methods. In this category, the searching process begins with one or more feasible points and continues to search for new points within the feasible region. When a new search point is generated and the point is not feasible, the point is repaired or discarded. When the feasible region is very small, generating initial feasible points is difficult and computationally demanding.
- (2) The constraint violation, which is the sum of the violation of all constraint functions, is combined with the objective function. The penalty function method is in this category [6-9]. In the penalty function method, an extended objective function is defined by adding the constraint violation to the objective function as a penalty. The optimization of the objective function and the constraint violation is realized by the optimization of the extended objective function. The main difficulty of the penalty function method is the selection of an appropriate value for the penalty coefficient that adjusts the strength of the penalty. If the penalty coefficient is large, feasible solutions can be obtained, but the optimization of the objective function will be insufficient. On the contrary, if the penalty coefficient is small, high quality (but infeasible) solutions can be obtained as it is difficult to decrease the constraint violation. In order to solve the difficulty, some methods, where the penalty coefficient is adaptively controlled, are proposed [5, 10, 11].
- (3) The constraint violation and the objective function are used separately. In this category, both the constraint violation and the objective function are optimized by a lexicographic order in which the constraint violation precedes the objective function. The rule of comparison where the constraint violation precedes the objective function is called *feasibility rule* and is a standard constraint-handling tech-

nique. Deb [12] proposed a method that adopts the extended objective function, which realizes the lexicographic ordering. Takahama and Sakai proposed the α constrained method [13] and the ε constrained method [14] that adopt a lexicographic ordering with relaxation of the constraints. Runarsson and Yao [15] proposed the stochastic ranking method that adopts the stochastic lexicographic order, which ignores the constraint violation with some probability. Mezura-Montes and Coello [16] proposed a comparison mechanism that is equivalent to the lexicographic ordering. Venkatraman and Yen [17] proposed a two-step optimization method, which first optimizes the constraint violation and then the objective function. These methods were successfully applied to various problems.

- (4) The constraints and the objective function are optimized by multiobjective optimization methods. In this category, the constrained optimization problems are solved as the multiobjective optimization problems in which the objective function and the constraint functions are objectives to be optimized [18-23]. But in many cases, solving multiobjective optimization problems is a more difficult and expensive task than solving single objective optimization problems.
- (5) Hybridization methods. In this category, constrained problems are solved by combining some of the above mentioned methods. Mallipeddi and Suganthan [24] proposed a hybridization of the methods in the categories (2), (3) and (4).

In this study, the category (2) is paid attention to. The EPC method is utilized for constrained optimization by PSO.

2.3. Penalty Function Methods

In the constrained optimization, it is necessary to optimize the objective function and the constraint violation simultaneously. In the penalty function method, the constrained optimization problem is converted to the following unconstrained optimization problem by adding the constraint violation $\phi(\mathbf{x})$ weighted by the penalty coefficient to the objective function $f(\mathbf{x})$ as a penalty.

$$F(\mathbf{x}) = f(\mathbf{x}) + \rho\phi(\mathbf{x}) \quad (2)$$

where $F(\cdot)$ is the extended objective function and ρ is the penalty coefficient ($\rho > 0$). By increasing the penalty coefficient towards ∞ , the constraint violation converges to 0, and an feasible solution can be obtained.

The constraint violation $\phi(\mathbf{x})$ satisfies the following:

$$\begin{cases} \phi(\mathbf{x}) = 0, & \text{if } \mathbf{x} \in \mathcal{F} \\ \phi(\mathbf{x}) > 0, & \text{if } \mathbf{x} \notin \mathcal{F} \end{cases} \quad (3)$$

Some types of constraint violations, which are adopted as a penalty in penalty function methods, can be defined as follows:

$$\phi(\mathbf{x}) = \max\{\max_j\{0, g_j(\mathbf{x})\}, \max_j|h_j(\mathbf{x})|\} \quad (4)$$

$$\phi(\mathbf{x}) = \sum_j(\max\{0, g_j(\mathbf{x})\})^p + \sum_j|h_j(\mathbf{x})|^p \quad (5)$$

where p is a positive number. In this study, Eq. (5) is used with $p = 1$.

There are three types of the penalty approaches: static penalty, dynamic penalty and adaptive penalty approaches. The value of the penalty coefficient is fixed in the static penalty approach, and it is changed dynamically according to the number of generations or iterations in the dynamic penalty approach. One needs to select a proper fixed value or proper changing schedule by trial and error, because the proper value and the proper schedule depend on the problem to be solved. In the adaptive penalty approach, the coefficient is changed based on information obtained from the population of solutions. The problem with the adaptive penalty approach is that some parameters for adaptive control of the penalty coefficient are introduced and proper parameter values still depend on the problems to be solved. Some approaches without the parameters are proposed. In [25], the normalization of the objective function and the constraint functions is proposed as follows:

$$\tilde{f}(\mathbf{x}) = \frac{f(\mathbf{x}) - f_{\min}}{f_{\max} - f_{\min}} \quad (6)$$

where f_{\min} and f_{\max} are the minimum value and the maximum value of f in the population, respectively.

$$\tilde{v}(\mathbf{x}) = \frac{1}{m} \sum_{j=1}^m \frac{v_j(\mathbf{x})}{v_{j,\max}} \quad (7)$$

$$v_j(\mathbf{x}) = \begin{cases} \max\{0, g_j(\mathbf{x})\}, & j = 1, \dots, q \\ |h_j(\mathbf{x})|, & j = q + 1, \dots, m \end{cases} \quad (8)$$

where $v_{j,\max}$ is the maximum value of v_j in the population.

$$F(\mathbf{x}) = \begin{cases} \tilde{f}(\mathbf{x}), & \text{if } \mathbf{x} \in \mathcal{F} \\ \tilde{v}(\mathbf{x}), & \text{if } R_f = 0 \\ \sqrt{\tilde{f}(\mathbf{x})^2 + \tilde{v}(\mathbf{x})^2} + A(\mathbf{x}), & \text{otherwise} \end{cases} \quad (9)$$

where R_f is the rate of feasible solutions in the population and $A(\mathbf{x}) = (1 - R_f)v(\mathbf{x}) + R_f\tilde{f}(\mathbf{x})$.

In [26], balancing the objective value and the constraint violations is proposed as follows:

$$F(\mathbf{x}) = \begin{cases} f(\mathbf{x}), & \text{if } \mathbf{x} \in \mathcal{F} \\ \tilde{f}(\mathbf{x}) + \sum_{j=1}^m k_j v_j(\mathbf{x}), & \text{otherwise} \end{cases} \quad (10)$$

$$\tilde{f}(\mathbf{x}) = \begin{cases} f(\mathbf{x}), & \text{if } f(\mathbf{x}) > \bar{f} \\ \bar{f}, & \text{otherwise} \end{cases} \quad (11)$$

where \bar{f} is the average of f in the population.

$$k_j = |\bar{f}| \frac{\bar{v}_j}{\sum_{l=1}^m \bar{v}_l^2} \quad (12)$$

where \bar{v}_j is the average of v_j in the population.

The EPC method will be explained in Section 4.

3. PARTICLE SWARM OPTIMIZATION

An animal such as an ant, a fish, and a bird has limited memory and ability to perform simple actions. In contrast, a group of animals such as an ant swarm, a fish

school, and a bird flock can take complex or intelligent actions such as avoiding predators and seeking foods efficiently. Swarm intelligence is defined as the collective actions of agents that act autonomously and communicate each other. PSO [27, 28] is a swarm intelligence based optimization method which is inspired by the movement of a bird flock. PSO imitates the movement to solve optimization problems and is considered as a population-based stochastic search method or POA.

Searching procedures by PSO can be described as follows: A group of agents minimizes the objective function f . At any time t , each agent i knows its current position \mathbf{x}_i^t and velocity \mathbf{v}_i^t . It also remembers its personal best visited position until now \mathbf{x}_i^* and the objective value $pbest_i$.

$$\mathbf{x}_i^* = \arg \min_{\tau=0,1,\dots,t} f(\mathbf{x}_i^\tau) \quad (13)$$

$$pbest_i = f(\mathbf{x}_i^*) \quad (14)$$

Two models, gbest model and lbest model have been proposed [29, 30]. In the gbest model, every agent knows the best visited position \mathbf{x}_G^* in all agents and its objective value $gbest$.

$$\mathbf{x}_G^* = \arg \min_i f(\mathbf{x}_i^*) \quad (15)$$

$$gbest = f(\mathbf{x}_G^*) \quad (16)$$

In the lbest model, each agent knows the best visited position \mathbf{x}_l^* in the neighbors and its objective value $lbest_i$, where the neighbors are defined by a topology such as ring, mesh, star and tree topology.

$$\mathbf{x}_l^* = \arg \min_{k \in N_i} f(\mathbf{x}_k^*) \quad (17)$$

$$lbest_i = f(\mathbf{x}_l^*) \quad (18)$$

where N_i is the set of neighbor agents to i . The velocity of the agent i at time $t + 1$ is defined as follows:

$$\mathbf{v}_{ij}^{t+1} = w\mathbf{v}_{ij}^t + c_1 \text{rand}_{1ij}(\mathbf{x}_{ij}^* - \mathbf{x}_{ij}^t) + c_2 \text{rand}_{2ij}(\mathbf{x}_{lj}^* - \mathbf{x}_{ij}^t) \quad (19)$$

where $l = G$ in the gbest model, w is an inertia weight and rand_{kij} is a uniform random number in $[0, 1]$ which is generated in each dimension. c_1 is a cognitive parameter, c_2 is a social parameter which represent the weight of the movement to the personal best and the group/neighbors best respectively. Usually, the maximum velocity V_j^{\max} is specified to avoid too large velocity and $|v_{ij}| \leq V_j^{\max}$ is satisfied.

The position of the agent i at time $t + 1$ is given as follows:

$$\mathbf{x}_i^{t+1} = \mathbf{x}_i^t + \mathbf{v}_i^{t+1} \quad (20)$$

In linearly decreasing inertia weight (LDIW) method [31], the inertia weight w is linearly decreasing with the number of iterations as follows:

$$w = w_{\max} - (w_{\max} - w_{\min}) \frac{t}{T_{\max}} \quad (21)$$

where w_{\max} and w_{\min} are the maximum weight and the minimum weight for w , respectively. T_{\max} is the maximum number of iterations. Recommended values are $w_{\max}=0.9$, $w_{\min}=0.4$, $c_1=c_2=2$ and $V^{\max}=u_j$.

In constriction model [32], Eq.(19) is modified to guarantee the convergence of agents to a local optimum as follows:

$$v_{ij}^{t+1} = \chi[v_{ij}^t + c_1 \text{rand}_{1ij}(x_{ij}^* - x_{ij}^t) + c_2 \text{rand}_{2ij}(x_{Gj}^* - x_{ij}^t)] \quad (22)$$

$$\chi = \frac{2}{\varphi - 2 + \sqrt{\varphi^2 - 4\varphi}} \quad (23)$$

$$\varphi = c_1 + c_2, \varphi > 4 \quad (24)$$

In [33], it is shown that the constriction model with $\chi=0.729$ and $c_1=c_2=2.05$ is equivalent to Eq.(19) with $w=0.729$ and $c_1=c_2=0.729 \times 2.05 = 1.49445$ and was performed well with using $V_j^{\max}=u_j$.

In this study, the constriction model is used for solving optimization problems.

4. PROPOSED METHOD

4.1. Equivalent Penalty Coefficient (EPC) Method

Let assume the POAs where a new solution \mathbf{x}'_i is compared with the old solution \mathbf{x}_i and the old solution is replaced with the new solution only if the new solution is better than the old solution. When both of the objective value and the constraint violation of \mathbf{x}'_i are better than those of \mathbf{x}_i , the value of the extended objective function of \mathbf{x}'_i is always better than that of \mathbf{x}_i , or $F(\mathbf{x}') < F(\mathbf{x})$ for any ρ , and vice versa. Also, if the objective values and the constraint violations are the same, $F(\mathbf{x}) = F(\mathbf{x}')$ holds for any ρ . Therefore, if the following conditions are satisfied, there is no need to determine the penalty coefficient.

$$\begin{aligned} f(\mathbf{x}') \leq f(\mathbf{x}) \text{ and } \phi(\mathbf{x}') \leq \phi(\mathbf{x}) \\ \text{or } f(\mathbf{x}) \leq f(\mathbf{x}') \text{ and } \phi(\mathbf{x}) \leq \phi(\mathbf{x}') \end{aligned} \quad (25)$$

Otherwise, there exist a solution with a better objective value and a worse violation value and a solution with a worse objective value and a better violation value. The equivalent penalty coefficient value (EPC) ρ_i is defined as the value that makes the extended objective values of \mathbf{x}_i and \mathbf{x}'_i the same:

$$F(\mathbf{x}_i) = F(\mathbf{x}'_i) \quad (26)$$

$$f(\mathbf{x}_i) + \rho_i \phi(\mathbf{x}_i) = f(\mathbf{x}'_i) + \rho_i \phi(\mathbf{x}'_i) \quad (27)$$

$$\rho_i = \frac{f(\mathbf{x}_i) - f(\mathbf{x}'_i)}{\phi(\mathbf{x}_i) - \phi(\mathbf{x}'_i)} \quad (28)$$

Let assume that $f(\mathbf{x}_i) < f(\mathbf{x}'_i)$ and $\phi(\mathbf{x}'_i) < \phi(\mathbf{x}_i)$. If the penalty coefficient is larger than ρ_i , $F(\mathbf{x}'_i) < F(\mathbf{x}_i)$ is satisfied and \mathbf{x}'_i is the better solution. On the contrary, if the penalty coefficient is smaller than ρ_i , $F(\mathbf{x}_i) < F(\mathbf{x}'_i)$ is satisfied and \mathbf{x}_i is the better solution.

Let consider the list of ρ_i sorted in ascending order, $H = \{\rho_k | \rho_k < \rho_{k+1}, k = 1, 2, \dots\}$ where $|H| \leq N$ and $|H|$ is the number of elements in H . In order to control the penalty coefficient simply and adaptively, an algorithm parameter R_{cp} ($R_{cp} \geq 0$), which is a constraint priority rate, is introduced. The coefficient ρ is decided as the $R_{cp}|H|$ -th element in H using linear interpolation,

because if $R_{cp}|H|$ is not integer such as 1.5, $\rho_{1.5}$ is not defined and can be obtained from ρ_1 and ρ_2 , as follows:

$$\rho = \begin{cases} R_{cp}|H|\rho_1, & \text{if } \lfloor R_{cp}|H| \rfloor < 1 \\ \rho_{\lfloor R_{cp}|H| \rfloor}, & \text{if } R_{cp} > 1 \\ \rho_{\lfloor R_{cp}|H| \rfloor} + \Delta R_{cp} \Delta \rho, & \text{otherwise} \end{cases} \quad (29)$$

$$\Delta R_{cp} = R_{cp}|H| - \lfloor R_{cp}|H| \rfloor \quad (30)$$

$$\Delta \rho = \rho_{\lceil R_{cp}|H| \rceil} - \rho_{\lfloor R_{cp}|H| \rfloor} \quad (31)$$

where $\lfloor \cdot \rfloor$ is rounding down to the nearest integer and $\lceil \cdot \rceil$ is rounding up to the nearest integer. The first equation in Eq.(29) is the interpolation between 0 and ρ_1 . When $R_{cp} = 0$, only the objective value will be optimized because $\rho = 0$. When $R_{cp} > 1$, only the constraint violation will be optimized because $\rho > \rho_{|H|}$ and the constraint violation has always higher priority than the objective value. Setting $R_{cp} > 1$ has similar effect of $\rho = \infty$ in the ordinary penalty function method. It is thought that a feasible solution can be found by changing R_{cp} to over 1 theoretically.

4.2. Adaptive Control of the Constraint Priority Rate

The EPC method can adaptively control the penalty coefficient using the fixed value of $R_{cp} = 0.9$ in problems without equality constraints. However, it is difficult to solve some problems with equality constraints. Therefore, an adaptive control of R_{cp} is introduced as follows:

$$R_{cp} = \begin{cases} R_{cp}^{\min}, & \text{if } R_f = 0 \\ R_{cp}^{\min} + (1 - R_{cp}^{\min})(1 - R_f), & \text{otherwise} \end{cases} \quad (32)$$

$$R_f = \frac{|\{\mathbf{x}_i | \phi(\mathbf{x}_i) = 0\}|}{|P|} \quad (33)$$

where R_{cp}^{\min} ($0 \leq R_{cp}^{\min} < 1$) is the minimum value of R_{cp} . If $R_f = 0$, that is, the population is far from the feasible region, $R_{cp} = R_{cp}^{\min}$ so that the population gradually approaches the feasible region. If $R_f > 0$, that is, the population is near the feasible region, R_{cp} is adaptively controlled so that the population does not leave the region. The recommended value of R_{cp}^{\min} is 0.9 which is determined based on some preliminary experiments.

4.3. Mutation and Repair

In this study, a mutation operation similar to rand/1 mutation of DE is utilized as follows:

$$\mathbf{x}_i^{\text{new}} = \mathbf{x}_{r1}^* + F(\mathbf{x}_{r2}^* - \mathbf{x}_{r3}^*) \quad (34)$$

where $r1$, $r2$ and $r3$ are random numbers in $\{1, 2, \dots, N\} \setminus \{i\}$, where N is the number of agents, and are different from each other. F is a scaling factor. A new position is created using personal best positions. It is expected that the mutation will help to move in a narrow feasible region. The mutation is applied with probability $P_m = 0.25$ based on some preliminary experiments.

When a new position is out of the search space, the position is repaired to be inside of the search space. The repaired position is the middle of the violated bounds and

the corresponding variables of the current position as follows:

$$x_{ij}^{\text{repaired}} = \begin{cases} \frac{1}{2}(l_j + x_{ij}^t) & x_{ij}^{t+1} < l_j \\ \frac{1}{2}(u_j + x_{ij}^t) & x_{ij}^{t+1} > u_j \\ x_{ij}^{t+1} & \text{otherwise} \end{cases} \quad (35)$$

Also, the velocity is changed so that the bounds are not violated again as follows:

$$v_{ij}^{\text{repaired}} = \begin{cases} -\frac{1}{2}v_{ij}^{t+1} & x_{ij}^{t+1} < l_j \text{ or } x_{ij}^{t+1} > u_j \\ v_{ij}^{t+1} & \text{otherwise} \end{cases} \quad (36)$$

4.4. The algorithm of the proposed method

The algorithm of the proposed method PSOEPC (PSO with EPC) is as follows:

1. Initializing agents: Initial agent i with a position \mathbf{x}_i and a velocity \mathbf{v}_i is created for all $i \in \{1, 2, \dots, N\}$ where N is the number of agents. \mathbf{x}_i is randomly generated in the search space \mathcal{S} where each element x_{ij} is a uniform random number in $[l_j, u_j]$. \mathbf{v}_i is initialized randomly where v_{ij} is a random number in $[-V_{\max_j}, V_{\max_j}]$ and $V_{\max_j} = \frac{1}{2}(u_j - l_j)$, which is half the range of j -th variable, in this study.
2. Evaluating agents: All agents i are evaluated and $f(\mathbf{x}_i)$ and $\phi(\mathbf{x}_i)$ are obtained. The personal best position is set to the initial position, namely $\mathbf{x}_i^* = \mathbf{x}_i$.
3. Obtaining the feasible rate: The feasible rate of personal best positions is obtained according to Eq.(33).
4. Termination condition: If the number of function evaluations exceeds the maximum number of function evaluations FE_{\max} , the algorithm is terminated.
5. Updating agents: Mainly, the agents are updated by the movement. The new velocity of each agent i are obtained according to Eq.(19). The each element of the new velocity is truncated in $[-V_{\max_j}, V_{\max_j}]$. The new position is obtained according to Eq.(20). Otherwise, with probability P_m , the agents are updated by the mutation according to Eq. (34). If the position is out of the search space, the position and the velocity is repaired according to Eqs. (35) and (36).
6. EPC method: ρ_i , R_{cp} and then ρ are determined according to Eqs. (28), (32) and (29) using the feasible rate.
7. Updating the personal best positions: The values of the extended objective function for the new positions and the best visited positions are obtained according to Eq. (2). If the extended objective value of the new position is better than that of the personal best position, the personal best position is replaced with the new position. If the extended objective value of the new position is better than that of the best position in all agents, the best position is set to the new position.
8. Go back to Step2.

5. SOLVING NONLINEAR OPTIMIZATION PROBLEMS

In this paper, thirteen benchmark problems that are mentioned in some studies [3, 15, 16] are optimized by the proposed method, or PSOEPC (PSO with EPC method).

5.1. Test problems and the experimental conditions

In the thirteen benchmark problems, problems g03, g05, g11 and g13 contain equality constraints. In problems with equality constraints, the equality constraints are relaxed and converted to inequality constraints according to Eq. (37), which is adopted in many methods:

$$|h_j(\mathbf{x})| \leq 10^{-4} \quad (37)$$

Problem g12 has disjointed feasible regions. Table 1 shows the outline of the thirteen problems [16, 34]. The table contains the number of variables D , the form of the objective function, the number of linear inequality constraints (LI), nonlinear inequality constraints (NI), linear equality constraints (LE), nonlinear equality constraints (NE) and the number of constraints active at the optimal solution.

Table 1 Summary of test problems

f	D	Form of f	LI	NI	LE	NE	active
g01	13	quadratic	9	0	0	0	6
g02	20	nonlinear	1	1	0	0	1
g03	10	polynomial	0	0	0	1	1
g04	5	quadratic	0	6	0	0	2
g05	4	cubic	2	0	0	3	3
g06	2	cubic	0	2	0	0	2
g07	10	quadratic	3	5	0	0	6
g08	2	nonlinear	0	2	0	0	0
g09	7	polynomial	0	4	0	0	2
g10	8	linear	3	3	0	0	6
g11	2	quadratic	0	0	0	1	1
g12	3	quadratic	0	9 ³	0	0	0
g13	5	nonlinear	0	0	1	2	3

Settings for PSO are as follows: The constriction model with $w=0.729$ and $c_1=c_2=1.49445$ is adopted. The number of agents $N = 50$ and the maximum number of function evaluations $FE_{\max} = 200,000$. Settings for the mutation are as follows: The mutation rate $P_m=0.25$ and scaling factor F is randomly generated in $[0.4,0.9]$. Settings for EPC method are as follows: Every constraint violation is defined as a simple sum of constraints, or $p = 1$ in Eq. (5). The R_{cp} is controlled using Eq. (32) with $R_{cp}^{\min} = 0.9$.

In this paper, 30 independent runs are performed.

5.2. Experimental results

In the experiments, several methods are examined: PSO with the feasibility rule (PSO), PSOEPC without the mutation (PSOEPC), PSO with the mutation (PSOm) and PSOEPC with the mutation (PSOEPCm). Two representative topologies, or fully-connected topology (gbest) and the ring topology (ring), are also examined. In the ring topology, the neighborhood size is 3, that is, i -th agent is connected to $(i-1)$ -th and $(i+1)$ -th agent.

Table 2 shows results of the best, median, mean, worst values and the standard deviation for the above methods.

The success rate, which is the ratio of finding a feasible solution in 30 runs, is shown in parentheses.

All methods found optimal solutions in all 30 runs for g_{04} and g_{12} . As for g_{01} , PSO, PSOm, PSOEPC and PSOEPCm with the ring topology found the optimal solutions in all 30 runs. As for g_{02} , PSOEPCm (ring) attained the best results. As for g_{03} , g_{07} , g_{10} and g_{13} , PSOEPCm (ring) attained the best results. As for g_{05} , PSOEPCm (gbest) and PSOEPCm (ring) attained the best results and found the optimal solutions in all runs. As for g_{06} and g_{11} , PSOEPC (ring), PSOm with both topologies and PSOEPCm with both topologies found the optimal solutions in all runs. As for g_{08} , all methods except for PSOEPC (gbest) found the optimal solutions in all runs. As for g_{09} , PSOm with both topologies and PSOEPCm with both topologies found the optimal solutions in all runs. Therefore, it is thought that PSOEPCm (ring) is the best method which find near optimal solutions in all runs for all problems except for g_{02} .

Wilcoxon signed rank test is performed and the result for each function is shown in Table 3. Symbols '+', '-', and '=' are shown when a method is significantly better than PSOEPC (ring), is significantly worse than PSOEPC (ring), and is not significantly different from PSOEPC (ring), respectively. Symbols '++' and '--' are shown when the significance level is 1% and '+' and '-' are shown when the significance level is 5%.

It is thought that EPC method is effective because PSOEPCm (ring) is significantly better than PSOm (ring) in 5 functions. It is thought that the mutation is effective because PSOEPCm (ring) is significantly better than PSOEPC (ring) in 9 functions. It is thought that the ring topology is effective because PSOEPCm (ring) is significantly better than PSOEPCm (gbest) in 5 functions. Thus, it is thought that the EPC method, the mutation and the ring topology is effective to constrained optimization.

6. CONCLUSIONS

In the penalty function method, feasible solutions can be found by increasing the penalty coefficient towards infinity theoretically, although it is difficult to do so computationally. In the EPC method, the penalty coefficient is controlled adaptively using the equivalent penalty coefficient (EPC) values. The constraint priority rate is defined to select a proper EPC value from EPC values and the adaptive control of the constraint priority rate using the feasible rate of the population is also defined.

In this study, the EPC method is introduced to PSO, the mutation and repair operations for PSO are defined, and PSOEPC is proposed. The experiments for solving well known constrained problems were performed and it was shown that PSOEPC could search for high quality solutions in all problems compare with standard methods.

In the future, we will apply EPC method to various real world problems that have large numbers of decision variables and constraints. Also, we will introduce the idea of EPC method into other POAs.
